## Module 4 Cheatsheet: JavaScript Programming for Web Applications Class or Method Description

Class or Method	Description	Example
appendChild()	An HTML DOM method that after creating an element, you can use this function to place the element in the appropriate location within the document. The element to append is the only parameter.	<pre>//Creates the element  and text "Hello World". Appends Hello World  to the HTML document. <head></head></pre>
Arrays	Created by declaring the array elements in []. An array can be assigned to a variable, usually using the keyword const or var.  Arrays use zero based indexing to access their elements.	<pre>const Beatles = ["Ringo", "Paul", "George", "John"]; //Here Beatles[0] is "Ringo".</pre>
Date()	Constructor is new Date([optional parameters]). If the constructor is declared with no parameters, it returns current local date and time. New dates can be created by passing parameters to new Date function.	<pre>//create a new date from a string var newDate = new Date("2021-1-17 13:15:30");  //create a new date instance representing 17 Jan 2021 00:00:00 //note that the month number is zero-based var newDate = new Date(2021, 0, 17);</pre>
document.createElement()	Takes one tag name parameter and creates an element with that name. Can place the element elsewhere on the page using functions like insertBefore(), appendChild(), replaceChild().	<pre>//Creates the element  and text "Hello World". Appends Hello World  to the HTML document. <head></head></pre>
<pre>document.createTextNode()</pre>	Takes a string as input text and returns a text node with the input text.	<pre>//Creates the element  and text "Hello World". Appends Hello World  to the HTML document. <head></head></pre>

about:blank 1/4

		<body onload="addPara()"></body>
document.getElementByID()	A method of the DOM that takes an ID value parameter and returns an element that matches the id.	<pre> //Changes the content of the div to "Hello World!" <div id="div1"></div></pre>
document.getElementsByTagName()	A method of the DOM that takes a tag name parameter and returns an array called "NodeList" that contains elements with the specified tag name.	<pre>//Gets an array of all elements in a document with the  tag. var tagNameArray = document.getElementsByTagName("p");</pre>
document.write()	Writes HTML or JavaScript to a document. Note that it overwrites any other text in the document so is mostly used for testing purposes only.	<pre>//Writes "Hello World" to the output stream. document.write("Hello World");</pre>
element.getAttribute()	Returns the value of the specified attribute. Takes one parameter: the attribute name whose value is to be returned.	<pre>//Removes the CSS style color blue <div id="div1" style="color: blue"></div> <script>   var div1 = document.getelementById("div1").getAttribute("style"); </script></pre>
element.innerHTML()	A property of the Element class that returns or alters contents of an HTML element as a text string.	<pre>//Changes the content of the div to "Hello World!" <div id="div1">   Hello   Hello   </div> </pre> <pre> <pre></pre></pre>
element.removeAttribute()	A property of the Element class that removes all previously set inline CSS styles for a particular element. Takes one parameter: the attribute name that is being removed.	<pre>//Removes the CSS style color blue <div id="div1" style="color: blue"></div> <script>   var div1 = document.getelementById("div1").getAttribute("style"); </script></pre>
element.setAttribute()	A property of the Element class that overwrites all previously set inline CSS styles for a particular element. Takes two parameters: the attribute name that is being set and the attribute value the attribute is set to.	<pre>//In all elements named "theImage" sets the name of all src attributes to "another.gif" document.getElementById("theImage").setAttribute("src",     "another.gif");</pre>
element.style()	A property of the Element class that returns or alters inline CSS. Syntax is element.style.propertyName = value	<pre>//Changes the CSS style color from blue to red <div id="div1" style="color: blue"></div> <script>   var div1 = document.getelementById("div1");   div1.style.color = "red"; </script></pre>

```
Instance creates two
                                  properties about the error:
                                  message that contains
                                  description of the error and
                                  the name property identifies //Catch statement defines a block of code to be
                                                             executed if an error occurs in the try block.
                                  the type of error. Generic
                                                             catch (err) {
                                  error plus 6 other core
                                                              document.getElementById("myfile").innerHTML =
Error Objects
                                  errors: TypeError,
                                                             err.name;
                                  RangeError, URIError,
                                  EvalError, ReferenceError,
                                                             //Creates custom error message
                                                             throw new Error("Only values 1-10 are permitted");
                                  SyntaxError.
                                  Error object can be
                                  extended to create custom
                                  error messages using the
                                  throw keyword.
                                  The history object is part of
                                  the window object and
                                  contains the URLs visited
                                  by the user within a
                                  browser window. It exposes //Go back two pages if the history exists in the
                                  useful methods and
History Objects
                                                             history list.
                                                             history.go(-2);
                                  properties that let you
                                  navigate back and forth
                                  through the user's history
                                  and manipulate the contents
                                  of the history stack.
                                  An HTML DOM method
                                  that, after creating an
                                  element, places a child
                                                             //Creates a new  element and places it in the
                                                             elementList before the first child of 
                                  element in the appropriate
                                                             let newLI = document.createElement("li");
                                  location before an existing
insertBefore()
                                                             newLI.innerText = "new Element";
                                  child. The method takes
                                                             let elementList = document.getElementById("thisList");
                                  two parameters, the node
                                                             elementList.insertBefore(newLI,
                                  object to be inserted and the elementList.childNodes[0]);
                                  existing node to insert
                                 before.
                                  The location object is part
                                                             //Returns the hostname property
                                  of the window object and
Location Objects
                                                             let myhost = location.hostname;
                                  contains information about
                                                             newLI.innerText = "new Element";
                                  the current URL.
                                  The navigator object is part
                                  of the window object class
                                  in the DOM that represents
                                  the client Internet browser,
                                                             //Retrieves the name of the browser
                                  also called the user agent.
Navigator Objects
                                                             var browsername = navigator.appName;
                                  There is no standard for this
                                  object so what it returns
                                  differs from browser to
                                  browser.
                                  A DOM event that starts a
                                                             //Executes myFunction after MyHTMLPage has been loaded
                                 method when a page is
                                                             document.getElementById("MyHTMLPage").onload = function
onload()
                                                             () {myFunction};
                                  loaded.
                                                             //Creates a new node and replaces the second element in
                                                             "thisList" with the word "blue"
                                  After creating an element,
                                                             let secondBullet = document.createTextNode("blue");
                                  this function replaces a
replaceChild()
                                                             var myList =
                                                             document.getElementById("thisList").childNodes[1];
                                  child node with a new node.
                                                             myList.replaceChild(secondBullet,
                                                             myList.childNodes[1]);
```

The screen object is part of the window object class in //Returns the height and width of the user's screen the DOM that can be used Screen Objects var height=screen.height; var width=screen.width; to return properties about the user's screen. The DOM window object is at the top of the DOM hierarchy and serves as the global object. Everything in //Opens a new browser window with the specified URL the DOM takes place in a Window Objects window.open("http://www.w3schools.com"); window. The window object controls the environment that contains the document. Opens a new window. The first parameter is a path, a URL, or an empty string, and optional parameters include the window name. features such as the placement of the window or the dimensions, and a Boolean replace value. The //Opens a new window that opens the IBM home page and feature parameter is a has a width of 600 and a height of 800) window.open() comma separated string of let thisWindow = window.open("http://www.ibm.com", "myWindow", "width"=600, "height"=800); name-value pairs and the replace parameter is an optional Boolean. This parameter has been deprecated so modern browsers may not support it. This method returns a reference to the new window object. Scrolls to a particular place in a window. Parameters //Scrolls the window to the pixel located at the include the x-coordinate window.scrollTo() coordinate (20, 200) which is the left-most pixel window.scrollTo(20, 200); and the y-coordinate which is the upper-most pixel. Primitive types can be //Enables the use of properties and methods of the converted to objects using String class such as the property n.length wrapper objects.
